Reasons to go beyond the Standard Model

- **Hierarchy problem**
Higgs mass receives arbitrarily large loop corrections in SM;
cancelled or at least truncated by new TeV-scale physics
- **Vacuum stability**
With $m_h = 125$ GeV, SM Higgs mass goes negative via
renormalisation group running at $E < M_{\text{GUT}}$
 \implies SM vacuum is unstable \implies new particles probably stabilise it
- **Dark matter**
Exists; absent in SM
- **Matter-antimatter asymmetry**
More matter than antimatter; no real SM mechanism
- **Neutrino masses**
Measured; absent in SM

Dark matter – properties & models

Must be:

- massive (gravitationally-interacting)
- unable to interact via the electromagnetic force (dark)
- non-baryonic
- “cold(ish)” (in order to allow structure formation)
- stable on cosmological timescales
- produced with the right relic abundance in the early Universe.

Good options:

- Weakly Interacting Massive Particles (WIMPs)
- sterile neutrinos
- gravitinos
- axions
- axinos
- hidden sector dark matter (e.g. WIMPless dark matter)

Dark matter – properties & models

Must be:

- massive (gravitationally-interacting)
- unable to interact via the electromagnetic force (dark)
- non-baryonic
- “cold(ish)” (in order to allow structure formation)

“The rest”

In order of (my own completely biased opinion of) usefulness for probing BSM physics:

- 1 **Neutrino physics (cosmological, solar, atmospheric)**
Masses, mixings, additional sterile neutrinos
Mass-generation models often require RH ν , extra symmetry groups
- 2 **BBN**
Extra particles can change elemental yields (decays, resonances, etc)
- 3 **Baryogenesis / Leptogenesis**
Baryon asymmetry may be generated by some new CP violation
May even be linked to dark matter production (‘asymmetric DM’)
- 4 **Inflation**
Eventually the inflaton needs to actually come from somewhere. . .

 - Coverage & optimisation vs contour mapping

Putting it all together: global fits

Goals:

- 1 given a particular theory, determine which parameter combinations fit all experiments, and how well
- 2 given multiple theories, determine which fit the data better, and quantify how much better

Issue 1: Combining fits to different experiments

Easy – composite likelihood ($\mathcal{L}_1 \times \mathcal{L}_2 \equiv \chi_1^2 + \chi_2^2$ for simplest \mathcal{L})

- LEP precision electroweak tests, limits on sparticle masses
- B -factory data (rare decays, $b \rightarrow s\gamma$), muon anomalous magnetic moment
- dark matter relic density from WMAP
- direct detection, indirect detection, LHC, BBN, etc

Putting it all together: global fits

Goals:

- 1 parameter estimation
- 2 model comparison

Issue 1: Combining fits to different experiments

- LEP precision electroweak tests, limits on sparticle masses
- B -factory data (rare decays, $b \rightarrow s\gamma$), muon anomalous magnetic moment
- dark matter relic density from WMAP
- direct detection, indirect detection, LHC, BBN, etc

Putting it all together: global fits

Issue 2: Including the effects of uncertainties in input data
Easy – treat them as *nuisance parameters*

Issue 3: Finding the points with the best likelihoods
Tough – MCMCs, nested sampling, genetic algorithms, etc

Issue 4: Comparing theories
Depends – Bayesian model comparison, p values
(TS distribution? \rightarrow coverage???)

Putting it all together: global fits

 - Coverage & optimisation vs contour mapping

First BSM global fits 2004–06

Started with Baltz & Gondolo (2004), Allanach & Lester (2006), Ruiz, Roszkowski & Trota (2006)

- Supersymmetric models – mSUGRA/CMSSM ($m_0, m_{1/2}, A_0, \tan \beta$)
- MCMC-based analyses – likelihood maps and Bayesian posteriors

2008-09

- MultiNest – Faster posterior sampling (Feroz & Hobson, Trotta et al 2008)
- Improved frequentist analyses – profile likelihood (Trotta et al 2008, Akrami, PS et al 2009, Mastercode 2009+)

Theories/Models: Please, anything but the CMSSM!

- General low-energy SUSY
(AbdusSalam et al 2010)
- Small perturbations on CMSSM:
NUHM1, NUHM2, VCMSSM
(Roskowski et al 2009,
Mastercode 2009+)
- CNMSSM / NmSUGRA
Extra SM singlet + singlino
(Lopez-Fogliani et al 2009)
- Universal Extra
Dimensions
with Kaluza-Klein DM
(Bertone et al 2010)

Addition of LHC data

1–5 fb⁻¹ data, 7–8 TeV centre of mass energy (2011-12)

- ATLAS/CMS LHC searches for supersymmetry
- Higgs signals

SuperBayes

MasterCode

Fittino

Gamma-rays

Gamma-ray annihilation searches have been added to the global fits:

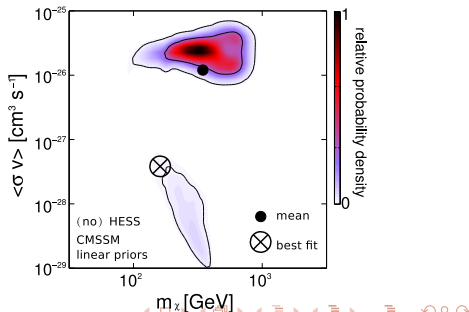

Fermi-LAT

Satellite pair conversion telescope
 Dwarf galaxy Segue 1
 (PS, Conrad et al 2009)

HESS

Air Čerenkov telescope
 Milky Way+Carina+Sculptor+Sag dwarf
 (Ripken, Conrad & PS 2011)

Direct detection data in global fits

XENON-100 bounds now maybe starting to impact BSM theories (Strege et al 2011, Mastercode 2011+, Fittino 2012)

– depends strongly on hadronic uncertainties

Tonne-scale detection could allow us to zoom in very quickly on the correct parameters (Akrami, Savage, PS et al 2011b)

Combined Direct + Indirect + LHC constraints

Base Observables

Combined Direct + Indirect + LHC constraints

Base Observables + XENON-100

Grey contours correspond to Base Observables *only*

Combined Direct + Indirect + LHC constraints

Base Observables + XENON-100 + CMS 5 fb^{-1}

Grey contours correspond to Base Observables *only*

Combined Direct + Indirect + LHC constraints

Base Observables + XENON-100 + CMS 5 fb⁻¹
+ IC22 × 100

Grey contours correspond to Base Observables *only*

CMSSM, IceCube-22 with 100× boosted effective area
(kinda like IceCube-DeepCore)

Outline

- 1 The Problem
 - Moving beyond the Standard Model
 - Beyond the SM with astroparticle probes
 - Global fits
- 2 Progress
 - Global fits beyond the SM
 - Indirect detection of dark matter
 - Direct detection of dark matter
- 3 Future Challenges
 - **Respectable LHC and astro likelihoods**
 - Parameter space \rightarrow Theory space
 - Coverage & optimisation vs contour mapping

Getting LHC data into global fits

Typical workflow in a collider phenomenology analysis:

- 1 Choose your new symmetries or effective operators
- 2 Augment SM Lagrangian with new terms
- 3 Derive Feynman rules
- 4 Derive/calculate cross-sections
- 5 Simulate events – parton showering
- 6 Simulate events – hadronisation
- 7 Rescale rates due to neglected loops (or other reasons)
- 8 Do ‘fast’ detector simulation of events to get final predicted rate
- 9 Repeat steps 5-8 for each point in parameter space

The LHC monster

Time per point:

$\mathcal{O}(\textit{minute})$ in **best** cases

The LHC monster

Time per point:

$\mathcal{O}(\textit{minute})$ in **best** cases

Time per point for global fits to converge:

$\mathcal{O}(\textit{seconds})$ in **worst** cases

The LHC monster

Time per point:

$\mathcal{O}(\textit{minute})$ in **best** cases

Time per point for global fits to converge:

$\mathcal{O}(\textit{seconds})$ in **worst** cases

Challenge:

About 2 orders of magnitude too slow to actually include LHC data in global fits properly

Taming the LHC monster

Zeroth Order Response:

“Stuff it, just use the published limits and ignore the dependence on other parameters”

Taming the LHC monster

Zeroth Order Response:

“Stuff it, just use the published limits and ignore the dependence on other parameters”

Obviously naughty – plotted limits assume CMSSM, and fix two of the parameters

- Don't really know dependence on other parameters
- Don't have a likelihood function, just a line
- Can't use this at all for non-CMSSM global fits – e.g. MSSM-25

Those in the room having done this can remain unidentified ☺

Taming the LHC monster

First Order Response:

“Test if things depend on the other parameters (hope not),
re-simulate published exclusion curve”

Taming the LHC monster

First Order Response:

“Test if things depend on the other parameters (hope not), re-simulate published exclusion curve”

Not that great, but OK in some cases

- At least have some sort of likelihood this time
- Still a bit screwed if things do depend a lot on other parameters, but
- allows (potentially shaky) extrapolation, also to non-CMSSM models

Fittino, Mastercode

Taming the LHC monster

Negative Order Response:

“I am such an übersmart particle theorist that I know much more about statistics than all those silly experimentalists and global fitters put together.

“I’ll just do an undersampled random scan and count the points, that way I don’t need to worry about all this sampling/statistics nonsense!”

Taming the LHC monster

Negative Order Response:

“I am such an übersmart particle theorist that I know much more about statistics than all those silly experimentalists and global fitters put together.

“I’ll just do an undersampled random scan and count the points, that way I don’t need to worry about all this sampling/statistics nonsense!”

(Sadly, people do think like this – and continue to publish such papers. I fight with them at meetings.)

Taming the LHC monster

Second Order Response:

“That’s ridiculous. I’ve never met a calculation I can’t speed up.
There must be some way to have my cake and eat it too”

Taming the LHC monster

Second Order Response:

“That’s ridiculous. I’ve never met a calculation I can’t speed up.
There must be some way to have my cake and eat it too”

Maybe – this is the challenge.

- Interpolated likelihoods (how to choose nodes?)
- Neural network functional approximation (how to train accurately?)
- Some sort of smart reduction based on event topology?
- Something else?

Two different approaches to including astro data in BSM scans

- 1 Just use the published limits on $\langle\sigma v\rangle$ (or $\sigma_{SI,SD}$)
 - Fast – can cover large parameter spaces
 - Not so accurate – experimental limits are invariably based on theoretical assumptions, e.g. $b\bar{b}$ spectrum
 - Full likelihood function almost never available
- 2 Use the data points directly in SUSY scans
 - Slow – requires full treatment of instrument profile for each point
 - Accurate – can test each point self-consistently
 - Allows marginalisation over theoretical assumptions
 - Allows construction of full multi-dimensional likelihood function

 - Accurate – can test each point self-consistently
 - Allows marginalisation over theoretical assumptions
 - Allows construction of full multi-dimensional likelihood function
- 3 (indirect only: use just flux upper limits)

Example: Advanced IceCube Likelihood (Part 1)

Simplest way to do anything is to make it a counting problem. . .

Compare observed number of events n and predicted number θ for each model, taking into account error σ_ϵ on acceptance:

$$\mathcal{L}_{\text{num}}(n|\theta_{\text{BG}} + \theta_{\text{sig}}) = \frac{1}{\sqrt{2\pi}\sigma_\epsilon} \int_0^\infty \frac{(\theta_{\text{BG}} + \epsilon\theta_{\text{sig}})^n e^{-(\theta_{\text{BG}} + \epsilon\theta_{\text{sig}})}}{n!} \frac{1}{\epsilon} \exp\left[-\frac{1}{2} \left(\frac{\ln \epsilon}{\sigma_\epsilon}\right)^2\right] d\epsilon. \quad (1)$$

Nuisance parameter ϵ takes into account systematic errors on effective area, from theory, etc. $\sigma_\epsilon \sim 20\%$ for IceCube.

Example: Advanced IceCube Likelihood (Part 2)

Full unbinned likelihood with number (\mathcal{L}_{num}), spectral ($\mathcal{L}_{\text{spec}}$) and angular (\mathcal{L}_{ang}) parts

$$\mathcal{L} = \mathcal{L}_{\text{num}}(n|\theta_{\text{signal+BG}}) \prod_{i=1}^n \mathcal{L}_{\text{spec},i} \mathcal{L}_{\text{ang},i} \quad (2)$$

with

$$\mathcal{L}_{\text{spec},i}(N_i, \Xi) = \frac{\theta_{\text{BG}}}{\theta_{\text{signal+BG}}} \frac{dP_{\text{BG}}}{dN_i}(N_i) + \frac{\theta_{\text{signal}}}{\theta_{\text{signal+BG}}} \int_0^{\infty} E_{\text{disp}}(N_i|E'_i) \frac{dP_{\text{signal}}}{dE'_i}(E'_i, \Xi) dE'_i \quad (3)$$

and

$$\mathcal{L}_{\text{ang},i}(\cos \phi_i) = \frac{\theta_{\text{BG}}}{\theta_{\text{signal+BG}}} \frac{dP_{\text{BG}}}{d \cos \phi_i}(\cos \phi_i) + \frac{\theta_{\text{signal}}}{\theta_{\text{signal+BG}}} \text{PSF}(\cos \phi_i|1) \quad (4)$$

Example: Advanced IceCube Likelihood (Part 2)

Full unbinned likelihood with number (\mathcal{L}_{num}), spectral ($\mathcal{L}_{\text{spec}}$) and angular (\mathcal{L}_{ang}) parts

$$\mathcal{L} = \mathcal{L}_{\text{num}}(n|\theta_{\text{signal+BG}}) \prod_{i=1}^n \mathcal{L}_{\text{spec},i} \mathcal{L}_{\text{ang},i} \quad (2)$$

with **Number of lit channels (energy estimator)**

$$\mathcal{L}_{\text{spec},i}(N_i, \Xi) = \frac{\theta_{\text{BG}}}{\theta_{\text{signal+BG}}} \frac{dP_{\text{BG}}}{dN_i}(N_i) + \frac{\theta_{\text{signal}}}{\theta_{\text{signal+BG}}} \int_0^{\infty} E_{\text{disp}}(N_i|E'_i) \frac{dP_{\text{signal}}}{dE'_i}(E'_i, \Xi) dE'_i \quad (3)$$

and

$$\mathcal{L}_{\text{ang},i}(\cos \phi_i) = \frac{\theta_{\text{BG}}}{\theta_{\text{signal+BG}}} \frac{dP_{\text{BG}}}{d \cos \phi_i}(\cos \phi_i) + \frac{\theta_{\text{signal}}}{\theta_{\text{signal+BG}}} \text{PSF}(\cos \phi_i|1) \quad (4)$$

Example: Advanced IceCube Likelihood (Part 2)

Full unbinned likelihood with number (\mathcal{L}_{num}), spectral ($\mathcal{L}_{\text{spec}}$) and angular (\mathcal{L}_{ang}) parts

$$\mathcal{L} = \mathcal{L}_{\text{num}}(n|\theta_{\text{signal+BG}}) \prod_{i=1}^n \mathcal{L}_{\text{spec},i} \mathcal{L}_{\text{ang},i} \quad (2)$$

with **Number of lit channels (energy estimator)**

$$\mathcal{L}_{\text{spec},i}(N_i, \Xi) = \frac{\theta_{\text{BG}}}{\theta_{\text{signal+BG}}} \frac{dP_{\text{BG}}}{dN_i}(N_i) + \frac{\theta_{\text{signal}}}{\theta_{\text{signal+BG}}} \int_0^\infty E_{\text{disp}}(N_i|E'_i) \frac{dP_{\text{signal}}}{dE'_i}(E'_i, \Xi) dE'_i \quad (3)$$

and

SUSY parameters

$$\mathcal{L}_{\text{ang},i}(\cos \phi_i) = \frac{\theta_{\text{BG}}}{\theta_{\text{signal+BG}}} \frac{dP_{\text{BG}}}{d \cos \phi_i}(\cos \phi_i) + \frac{\theta_{\text{signal}}}{\theta_{\text{signal+BG}}} \text{PSF}(\cos \phi_i|1) \quad (4)$$

Predicted signal direction (δ function at Sun)

Outline

- 1 The Problem
 - Moving beyond the Standard Model
 - Beyond the SM with astroparticle probes
 - Global fits
- 2 Progress
 - Global fits beyond the SM
 - Indirect detection of dark matter
 - Direct detection of dark matter
- 3 Future Challenges
 - Respectable LHC and astro likelihoods
 - **Parameter space \rightarrow Theory space**
 - Coverage & optimisation vs contour mapping

CMSSM, SMS \neq BSM

(SMS = Simplified Model Spectrum; used by ATLAS and CMS for results display due to complaints about CMSSM)

Want to do model comparison to actually work out which theory is right. . .

Challenge:

How do I easily adapt a global fit to different BSM theories?

CMSSM, SMS \neq BSM

(SMS = Simplified Model Spectrum; used by ATLAS and CMS for results display due to complaints about CMSSM)

Want to do model comparison to actually work out which theory is right. . .

Challenge:

How do I easily adapt a global fit to different BSM theories?

Somehow, we must recast things quickly to a new theory

- data
- likelihood functions
- scanning code 'housekeeping'
- even predictions

\implies a new, very abstract global fitting framework

Outline

- 1 The Problem
 - Moving beyond the Standard Model
 - Beyond the SM with astroparticle probes
 - Global fits
- 2 Progress
 - Global fits beyond the SM
 - Indirect detection of dark matter
 - Direct detection of dark matter
- 3 Future Challenges
 - Respectable LHC and astro likelihoods
 - Parameter space \rightarrow Theory space
 - Coverage & optimisation vs contour mapping

We don't *really* know the distribution of our test statistic in BSM global fits, as it is too expensive to Monte Carlo

- coverage is rarely spot-on unless mapping from parameters to data-space is linear
(Akrami, Savage, PS et al, Bridges et al 2011, Strece et al 2012)
- p -value assessments of goodness of fit should be viewed with scepticism (\rightarrow MasterCode)

Convergence remains an issue, especially for profile likelihood Messy likelihood \implies best-fit point can be (and often is) easily missed (Akrami, PS et al 2010, Feroz et al 2011)

- frequentist CLs are often off, as isolikelihood levels are chosen incorrectly
- can impact coverage (overcoverage, or masking of undercoverage due to non- χ^2 TS distribution)
- need to use multiple priors and scanning algorithms (one optimised for profile likelihoods?)

Closing remarks

- Robust analysis of dark matter and BSM physics requires multi-messenger global fits
- Lots of interesting astroparticle observables to include in global fits
- Quite a bit of technical (statistical/computational) detail to worry about

Ranked Challenges:

Closing remarks

- Robust analysis of dark matter and BSM physics requires multi-messenger global fits
- Lots of interesting astroparticle observables to include in global fits
- Quite a bit of technical (statistical/computational) detail to worry about

Ranked Challenges:

- 1 The LHC likelihood monster

Closing remarks
